Black photovoltaic inverter

Overview

Can PV power plants provide black start capability to photovoltaic power plants?

Existing solutions for providing black start capability to photovoltaic (PV) power plants rely on the use of energy storage systems (ESS) in a hybrid PV plant. In contrast, this paper proposes a solution for the contribution of PV power plants to the PSR that allows a completely autonomous black start process.

Why do PV inverters need a high DC voltage?

In order to be able to supply the demanded load, either increasing or decreasing the output power, the dc voltage at the PV inverters has to be above the maximum power point voltage. This results in a tradeoff between energy generation and the contribution of PV plants to power regulation.

What is the control system for the black-start of PV generators?

Based on the model presented in the previous section, the control system for the black-start of the PV generators is proposed in this section. The main objective of this control system is that the PV generators are able to operate in an isolated system, providing the active and reactive power demanded by the loads.

Can an inverter black-start a motor?

The inverter model is connected to an induction motor through transformers and a transmission line to simulate its startup. Simulation results show that even with the limited current supply capability of inverters because of their physical constraints, IBRs can black-start a motor under certain conditions.

Can a grid-forming inverter be used to black-start conventional generators?

The use BESS to black-start conventional generators has been demonstrated. The ability of a voltage source converter-based high voltage DC system to

black-start large inductive loads has also been tested. In addition, grid-forming inverter control with virtual oscillator has demonstrated potential black-start capability with grid-forming IBRs.

How do PV inverters affect reactive power demand?

The new demand is supplied equally by both inverters. As a consequence of the load increase, there is a voltage drop, following the APS control law. Due to the change in voltage at the PV inverters filter capacitor, there is a variation of reactive power demand (around 0.03 pu).
