Cooling air for air-cooled generator

Overview

In air-cooling systems, the engine takes cool air from the atmosphere and blows it internally across the different parts of the generator set. This keeps the generator from overheating.

In air-cooling systems, the engine takes cool air from the atmosphere and blows it internally across the different parts of the generator set. This keeps the generator from overheating.

Air cooled generators are produced in two basic configurations: Open ventilated (OV) - In the OV design, outside air is drawn directly from outside the unit through filters, passes through the generator and is discharged outside the generator. Totally enclosed water to air cooled (TEWAC) - In the TEWAC design, air is circulated within the generator, passing through frame-mounted air to water heat exchangers.
