Microgrid primarily operates in two modes of operation— islanded mode or grid-connected. The latter can further be subclassified into power matched or mismatched operation that can be understood with the help of point of common coupling (PCC) (Fig. 1.8).

There are four classes of microgrids: single facility microgrids, multiple facility microgrids, feeder microgrids, and substation microgrids. Distributed energy resources (DERs) are divided into two groups based on the type of interface with the microgrid.

Modeling of microgrid is a key aspect and the recent developments in the modeling of microgrid are presented in both grid-connected and autonomous mode. The control techniques of microgrid available in the literature for various modes of operation are also discussed.

“A microgrid is a group of interconnected loads and distributed energy resources within clearly defined electrical boundaries that acts as a single controllable entity with respect to the grid. A microgrid can connect and disconnect from the grid to enable both grid-connected and island-modes of operation .”
