How microgrids work

Overview

A microgrid presents various types of generation sources that feed electricity, heating, and cooling to the user. These sources are divided into two major groups – thermal energy sources (e.g., natural gas or generators or) and renewable generation sources (e.g. wind turbines and solar).

A microgrid is a self-contained electrical network that allows you to generate your own electricity on-site and use it when you need it most. A microgrid is thus a type of distributed energy resource.

Microgrids are small-scale power grids that operate independently to generate electricity for a localized area, such as a university campus, hospital complex, military base or geographical region.

A microgrid, regarded as one of the cornerstones of the future smart grid, uses distributed generations and information technology to create a widely distributed automated energy delivery network.

How Do Microgrids Work?

The purpose of a microgrid is to safely separate energy from the main grid for on-demand use. To do this, one or more energy sites must be installed to serve a specific area.

Microgrids support a flexible and efficient electric grid by adapting to integrating growing deployments of renewables such as solar farms and electric vehicles. How does a microgrid work?

The electrical grid exists to supply our electricity demand, ensuring the two are balanced and connecting electrical supply to electrical demand with the transmission and distribution system. In practice, a microgrid works in the exact same way, just for a smaller geographic area, like a couple of buildings or a local community.

What is a remote microgrid?

A remote microgrid is a small-scale power system that can operate autonomously or in parallel with a main power grid. These systems can be customized to accommodate clean energy storage systems, such as solar panels. Off-grid microgrids can work autonomously on 'island mode', while a grid connected to a power grid can bolster what's known as 'grid resilience'. Another huge advantage to local power production is the optimization of heat energy.

What is the difference between a grid and a microgrid?

A grid is a large network of electrical power lines and generators that supplies power to homes and businesses, while a microgrid is a small, localized network of electrical power lines and generators that supplies power to a specific area, such as a single building or a group of buildings.

What happens if a microgrid is grid-connected?

If the microgrid is grid-connected (i.e., connected to the main electric grid), then the community can draw power from the main electric grid to supplement its own generation as needed or sell power back to the main electric grid when it is generating excess power.

Can microgrids bring electricity to all?

Most generate their own power using renewable energy like wind and solar. In power outages when the main electricity grid fails, microgrids can keep going. They can also be used to provide power in remote areas. A nun in the Democratic Republic of Congo is showing the world how microgrids can bring electricity to all.

How do microgrids manage energy?

Energy Management: Microgrids need a system to manage the flow of energy, ensuring that energy is being used efficiently and effectively. This includes monitoring and controlling the mix of energy sources, as well as balancing the energy supply and demand.
