How to adjust the balanced current of photovoltaic panels

Overview

Throughout the Code, when dealing with currents, we see the phrase “125% of the continuous currents plus 100% of the noncontinuous currents” [e.g. 210.19(A)(1), 215.1(A)(1)]. This Code requirement is used when calculating the ampacity of conductors and to some extent in the rating of overcurrent devices.

The NEC requirements for calculating conductor ampacities are designed to ensure that the conductors do not operate over 80% of their rating.

The dc currents produced by PV modules vary directly with sunlight intensity and when the irradiance exceeds 1000 W/m², the currents may exceed.

The author has retired from the Southwest Technology Development Institute at New Mexico State University but is devoting about 25% of his time to.

Since the short-circuit current is the highest current the PV module can produce (for any given value of irradiance), an adjustment is made to the rated short-circuit current of the PV module (at STC) before that current is used in calculations for ampacities and overcurrent devices.

To provide over current limitation as well as to ensure maximum exploitation of the inverter capacity, a control strategy is proposed, and performance the strategy is evaluated based on the three.

Inverter clipping, or “inverter saturation,” occurs when DC power from a PV array exceeds an inverter’s maximum input rating. The inverter may adjust the DC voltage to reduce input power, increasing voltage and reducing DC current. Alternatively, the inverter may restrict or throttle the inverter’s AC output. Inverter clipping is .

The solar charge controller (frequently referred to as the regulator) is identical to the standard battery charger, i.e., it controls the current flowing from the

solar panel to the battery bank to prevent overcharging the batteries. As in a standard battery charger, it can accommodate different types of batteries.

In this paper, an intelligent approach based on fuzzy logic has been developed to ensure operation at the maximum power point of a PV system under dynamic climatic conditions. The current distortion due to the use of static converters in photovoltaic production systems involves the consumption of reactive energy.
