How to check defects in generator blades

Overview

How to detect damage to gas turbine blades?

The external forms of damage to the gas turbine blades may be detected with a reliable and effective non-destructive visual method with the support of an optoelectronic device (video scope, borescope) without the need to dismantle the engine [1,5,7, . .

Why do gas turbine blades need to be inspected?

These blades face continuous thermal stress, making rigorous inspection essential to catch any flaws early. The multifaceted role of turbine blades in gas engines underscores their use to identify potential defects, which could impair performance or compromise safety. Blade integrity is fundamental to a gas turbine engine's safe operation.

What are the failures of gas turbine blades?

A detailed summary of the above discussed gas turbine blades failures is presented in Table 1. Table 1. Failure analysis survey of gas turbine blades. Separation of a blade at the top firtree. Impact induced by the separation of the first blade. Materials poor quality. Removal of scale and coating due to high rates of erosion.

Can AI detect a gas turbine blade?

However, the range of defects that can be detected is still limited. Typically, neu-]. However, they require significant There exist several commercial AI software for inspection of gas turbine blades. Some focus on borescope inspection []. They all use Deep Learning AI, which is perhaps feasible tive blade images.

How do you ensure quality turbine blade inspections?

Ensuring quality turbine blade inspections involves selecting suitable NDT methods, skilled inspectors, and precise equipment calibration. Understanding

potential defect types and adhering to standard procedures is essential. Leveraging advanced technologies and keeping abreast of new methods also improves inspection outcomes.

Do Ni-based gas turbine rotor blades fail?

Kumari et al. analysed the failure of four Ni-based gas turbine rotor blades, as displayed in Fig. 7a and 7b, that are strengthened with γ' phase ($\text{Ni}_3(\text{Al,Ti})$). At creep temperatures ($>0.4 T_m$), microstructural changes such as directional growth of γ' and coarsening, formation of carbide films along the grain boundaries do take place.
