we propose a charging station recommendation algorithm with constraints of the power load degree of microgrids. The algorithm prevents a large-scale influx of EVs into a small number of charging stations for charging service and avoids the sharp increase of the charging load and hence optimizes.

By using BSS to manage the charging of EVs, microgrids can mitigate grid congestion issues caused by multiple EVs charging simultaneously. BSS can distribute the charging load intelligently, considering grid constraints and available capacity, to prevent overloading and ensure a reliable power supply to both EVs and other critical loads [23].

A charging/discharging algorithm is suggested to find the number of EVs that minimizes the overall consumption of electrical energy drawn from the grid. A case study for the Microgrid (MG) system at Jordan University of Science and Technology (JUST) is used to illustrate the proposed algorithm.

To efficiently schedule the addressed process, in this work, we consider the matching between an EV and a charging pile instead of the matching between an EV and a charging station, since a station may contain multiple charging piles. With this consideration, a charging pile is assigned to an EV by the scheduling center.
