Microgrid PCC point switch

Overview

What is the difference between PCC and microgrid?

In grid interfaced mode of operation, PCC is closed and microgrid is linked with utility grid. Whenever there is any disturbance in utility grid or microgrid, PCC is opened and a microgrid is disconnected to the main grid, then the microgrid is operated in stand-alone mode [11]. There are two types of microgrids available.

How is a microgrid operated?

It is operated either in stand-alone mode or grid connected mode [2, 3]. Microgrid can be defined as a system or a subsystem, which incorporates single, or multiple sources, controlled demands, energy storage systems, security and supervision system. These elements and subsystems make microgrid operational in utility integrated or isolated mode.

What are the points of common coupling of microgrids?

Points of common coupling of Microgrids #1, #2, and #3 are PCC1, PCC2, and PCC3, respectively. Points of common coupling are configured with the same grid connection interface devices, which are designed in low voltage switch cabinets. Refer to Figs. 6.4 and 6.6 for details. The principle of active island is introduced in Section 3.1.

What is microgrid power system?

Microgrid power system Microgrid system is a configuration of single or multiple renewable energy sources with even nonconventional sources as main energy generation source, so that the capacity shortage of power from one source will substitute by other available sources to provide sustainable power.

Is island mode possible with SEL microgrid control systems?

A seamless transition to island mode operation is possible when this system is

used in conjunction with SEL microgrid control systems. Two variations of these systems are available: simplified controls using only SEL protective relays or, alternatively, pre-engineered library modules for the SEL Real-Time Automation Controller (RTAC) family.

What are the parts of a microgrid control system?

In the microgrid control system, there are main parts including: microsource controllers (MCs) on the consumer production side and load controllers (LCs) on the consumer demand side; microgrid system central controller (MGCC) on the middle of the main grid; and microgrid structures and distribution management system (DMS) in the grid network side.
