Photovoltaic inverter IGBT more than 100 degrees

Overview

How much damage does a photovoltaic inverter cause?

When the optimal PV system capacity ratio and power limit value are taken, the annual damage of the IGBT in the photovoltaic inverter is 0.847% and the net increase of power generation is 8.31%, realizing the increase of photovoltaic power generation while the annual damage of IGBT and power generation loss due to power limit is relatively low.

How to improve PV inverter lifetime?

In response to this problem, the literature proposed a novel control strategy to limit the power generation, thereby improving the PV inverter lifetime. For a specific photovoltaic inverter system, there should be an optimal PV system capacity ratio and power limit value, taking into account inverter damage and increasing power generation.

Why are photovoltaic panels rated higher than inverters?

The literature considers the capacity ratio of photovoltaic panels, and designs the rated power of photovoltaic arrays higher than that of photovoltaic inverters, so that more power can be generated during off-peak periods. However, during the peak period, the PV output power is large, thus causing damage to the photovoltaic inverter.

Are insulated-gate bipolar transistors a good choice for solar inverter applications?

For solar inverter applications, it is well known that insulated-gate bipolar transistors (IGBTs) offer benefits compared to other types of power devices, like high-current-carrying capability, gate control using voltage instead of current and the ability to match the co-pack diode with the IGBT.

Can a control strategy improve a photovoltaic inverter lifetime?

However, during the peak period, the PV output power is large, thus causing

damage to the photovoltaic inverter. In response to this problem, the literature proposed a novel control strategy to limit the power generation, thereby improving the PV inverter lifetime.

How do IGBTs work in a PV inverter?

During operation inside a PV inverter, IGBTs are subject to AC stress conditions as opposed to DC stress conditions. This typically consists of a 60 Hz on-off cycle, with a Pulse-Width-Modulated (PWM) signal on the order of 10 - 15 kHz superimposed on the lower-frequency cycle.
