# Photovoltaic inverter has reactive power at night

## Overview

---

Grid-tie inverters can be regarded as the main component in both renewable-energy conversion systems and smart grid systems. They can convert renewable energy into power that then can be fed to the utility grid as long as the renewable source exists. For photovoltaic (PV) inverters, solar energy must be there to generate.

In the modern day, the PV inverters are being developed under the interconnection standards such as IEEE 1547, which do not allow for voltage.

In this section, the MATLAB®/Simulink® simulation model of the novel design is presented by considering three different scenarios of the power system. The design will be validated.

The controlling mechanism of the novel concept with a background study is described under this topic. Further, the methods used for the design are described in detail.

The hardware implementation with output results of the novel three-phase inverter model is discussed in this section. Fig. 9 shows the block diagram.

In order for the PV system to also be able to feed in reactive power at night, the inverter must be fitted with the "Q at Night" option.

In order for the PV system to also be able to feed in reactive power at night, the inverter must be fitted with the "Q at Night" option.

Photovoltaic (PV) inverters are able to provide reactive power in a decentralized manner at the grid-connection point even outside active power feed-in operation, especially at night.

Certain inverters are designed to operate in volt-ampere reactive (VAR) mode during the night.

The PV inverters are not utilized at the night peak. Therefore, it can be operated in feeding reactive power to eliminate the low voltage occurrence during the night peak.
