In a grid-connected PV system, the injected currents are controlled by the inverter, and thus, maintains the DC-link voltage to its reference value and regulates the active and the reactive power d.

For a grid-connected PV system, inverters are the crucial part required to convert dc power from solar arrays to ac power transported into the power grid. The control performance and stability of inverters severely affect the PV system, and lots of works have explored how to analyze and improve PV inverters' control stability [ 6 ].

Abstract: This work presents the design of a control to regulate the active and the reactive power in single-phase PV inverters. The control is composed by an inner loop with a passivity-based control in charge to track the current reference generated by the outer loop and PI controllers in the outer loop that regulate the power injection of .

This paper will demonstrate the operation of a PV inverter in reactive power-injection mode when solar energy is unavailable. The primary focus is on the design of the inverter controller with respect to the synchronous rotating frame control method.
