Overview

How does Sam calculate a photovoltaic performance model?

SAM's photovoltaic performance model calculates the hourly AC output of the photovoltaic system. It then adds up these 8,760 hourly values to calculate the system's total AC output in one year. This value is treated as the system's total output in the first year of the system's operation.

What is a Photovoltaic Performance Model?

A Photovoltaic Performance Model is a tool that can simulate any size of photovoltaic system, from a small rooftop array and a single inverter to a large system with multiple subarrays and banks of inverters. It calculates the system's AC electrical output as an array of 8,760 hourly AC power values over one year.

What is insolation in a photovoltaic array?

Insolation is a measure of the energy from the sun on a surface, given in watt-hours per square meter (Wh/m²). SAM calculates the monthly and annual insolation incident on the plane of the photovoltaic array (Section 6).

How does Sam calculate the DC output of a photovoltaic array?

SAM calculates the DC output of a photovoltaic array by multiplying a single module's DC output (Section 9) by the number of modules in the array. This assumes that all of the modules in the array operate uniformly at the maximum power point of a single module.
