Triboelectric nanogenerator (TENG) technology is a promising alternative for wind energy harvesting 20, 21. TENGs were introduced in 2012 as a new way of harvesting mechanical energy from .

As the name suggests, indirect drive wind turbines transfer the mechanical energy to the generator through a series of gears instead of a direct rotor-to-generator drive. With the aid of gears, this drive mechanism provides faster speeds at the generator end, enabling the use of relatively smaller generators.

This study aims to conduct comparative analyses on WECS technologies (with different generators, and PECs) based on their energy harvesting capability, cost-effectiveness, and advances in designs. Assessments of the approaches and strategies for smoothing power production are also presented.

A new Berkley Lab analysis finds that despite an expected future reduction in the number of turbines per power plant, the total estimated annual energy output of wind plants will increase due to larger, more powerful wind turbines.
