

European Solar and Energy Storage Solutions

Schematic diagram of air-cooled energy storage system

Overview

What is compressed air energy storage?

Overview of compressed air energy storage Compressed air energy storage (CAES) is the use of compressed air to store energy for use at a later time when required , , , . Excess energy generated from renewable energy sources when demand is low can be stored with the application of this technology.

What are the stages of a compressed air energy storage system?

There are several compression and expansion stages: from the charging, to the discharging phases of the storage system. Research has shown that isentropic efficiency for compressors as well as expanders are key determinants of the overall characteristics and efficiency of compressed air energy storage systems .

What is the enthalpy transformation of air in compressed air energy storage systems?

The enthalpy transformation of air in the various types of compressed air energy storage systems varies depending on the expansion trajectories. The expansion stage for diabatic and adiabatic compressed air energy storage systems are described as isentropic processes that occur in the absence of heat transfer within the environment.

What is a diabatic compressed air energy storage system?

For diabatic compressed air energy storage systems, with the application of isochoric compressed air storage, the pressure in the cavern must be throttled, even though it often exceeds the pressure in the combustion chamber.

How does a thermal energy storage system work?

There is cooling of the air as it flows via the thermal energy storage device,

followed by an after-cooler. From this stage, there is compression of the air until required pressure is achieved. This means that the temperature of the air is again raised to 380 °C. There is an exchange of heat in the second thermal energy storage system.

What is adiabatic compressed air energy storage system?

For the advanced adiabatic compressed air energy storage system depicted in Fig. 11, compression of air is done at a pressure of 2.4 bars, followed by rapid cooling. There is considerable waste of heat caused by the exergy of the compressed air. This occurs due to two factors.
