The movement of electrons, which all carry a negative charge, toward the front surface of the PV cell creates an imbalance of electrical charge between the cell's front and back surfaces.

The movement of electrons, which all carry a negative charge, toward the front surface of the PV cell creates an imbalance of electrical charge between the cell's front and back surfaces.

The two dissimilar semiconductors possess a natural difference in electric potential (voltage), which causes the electrons to flow through the external circuit, supplying power to the load.

Solar technologies convert sunlight into electrical energy either through photovoltaic (PV) panels or through mirrors that concentrate solar radiation.

Here's how it works: There are two layers of silicon in solar cells. This electric field knocks electrons loose from the atoms in solar cells, setting them in motion. The electrons flow through the solar cell and out of the junction, generating an electrical current. □□□□.

Here's how a solar panel system works: When sunlight strikes the silicon solar cells, it knocks electrons loose, setting them in motion and creating a flow of electric current. Wires then capture this direct current (DC) electricity and feed it to a solar inverter. □□□□
