What is a solar-assisted ground source heat pump system?

Entchev et al. (2014) proposed a solar-assisted ground source heat pump system for space heating, space cooling, DHW, and electricity generation. The system consisted of PVT collectors, a solar tank, a hot-water tank, a cold-water tank, and a ground source heat pump with boreholes.

How does a heat pump integrate with a solar plant?

The integration of the heat pump unit allows to increase the solar fraction up to 77–95%; The HP integration leads to a slight increase of the storage efficiency of the seasonal tank. At the same time, the energy collected by the solar plant increases, and the overall thermal losses of the tank decrease.

Are heat pumps combined with solar renewable heat?

Table 1 summarises the studies on heat pumps combined with solar renewable heat. From the analysis of the data given in this table, it can be concluded that most studies have focused on combined PV/T heat pump technologies because PV/T panels provide electrical and thermal energy.

Can a modulating heat pump be integrated into a solar system?

The integration of a modulating heat pump unit with proportional control into the solar system with seasonal storage was found to be a beneficial solution in case of small tank sizes and limited solar collector areas.

Can a water-source heat pump be used as a heat source?

In combination with seasonal storage tanks, a promising solution is the use of water-source heat pump to use the heat in the tank as a heat source for the HP. This application can lead to several advantages. First of all, the heat pump works with higher performance because of the high temperature of the heat source.

How does a solar heat pump work?

The seasonal tank stores the solar energy collected during the summer, which is used to directly provide space heating to the house, until the water temperature drops below 30 °C. At that point, the heat pump starts operating exploiting the residual heat in the tank as a heat source.
