# What altitude is suitable for wind power generation

## Overview

---

The highest wind power densities are found at altitudes between 8,000 and 10,000 m above ground, corresponding roughly to the height of the tropopause.

The highest wind power densities are found at altitudes between 8,000 and 10,000 m above ground, corresponding roughly to the height of the tropopause.

We find wind turbines placed on Earth's surface could extract kinetic energy at a rate of at least 400 TW, whereas high-altitude wind power could extract more than 1,800 TW.

The highest wind power densities are found at altitudes between 8,000 and 10,000 m above ground, corresponding roughly to the height of the tropopause. The 10,000 m altitude appears to be the maximum height that is worth exploring for high-altitude wind power technologies.

Estimated power generation is about 800 kW between ground level and 800 meters with varying wind speeds up to 24 m/s. [5] A kite with area up to 500 m<sup>2</sup> could generate 2 MW of power with a constant windspeed of 9 m/s and exponentially more power with higher wind speeds.

A host of start-up companies are exploring ways to harness the enormous amount of wind energy flowing around the earth, especially at high altitudes. But as these innovators are discovering, the engineering and regulatory challenges of what is known as airborne wind power are daunting. What is the highest altitude for wind power?

Can a wind turbine harness higher altitude winds?

Although below 1000 feet, the development of an airborne turbine is promising for harnessing even higher altitude winds. Makani hopes to have a 600 kW capable device by 2016. Kitegen, a wind power engineering company based out of Italy, has been prototyping kite powered generators since 2007.

How can high altitude wind be harnessed?

With the realization of the potential of high altitude wind, there are considerable efforts to harness the steady and fast blowing winds of the jet streams. Two emerging prototype stage technologies are Makani Power and Kitegen Energy Systems.

Is high altitude wind a viable option?

Consistency is of large concern when assessing the potential of high altitude wind. If the high velocity wind is full force for a short time annually it is not a viable option over land-based turbines.

What is the average height of a wind turbine?

Wind speeds are slower close to the Earth's surface and faster at higher altitudes. Average hub height is 98m for U.S. onshore wind turbines 7, and 116.6m for global offshore turbines 8.

Why is wind power more consistent at high altitudes?

At this height the ABM is exposed to higher velocity, steadier and more persistent winds, therefore resulting in a higher consistency of power generation . The profile of wind power densities with respect to altitudes between 500 m and 12,000 m have been assessed globally .
